Introduction

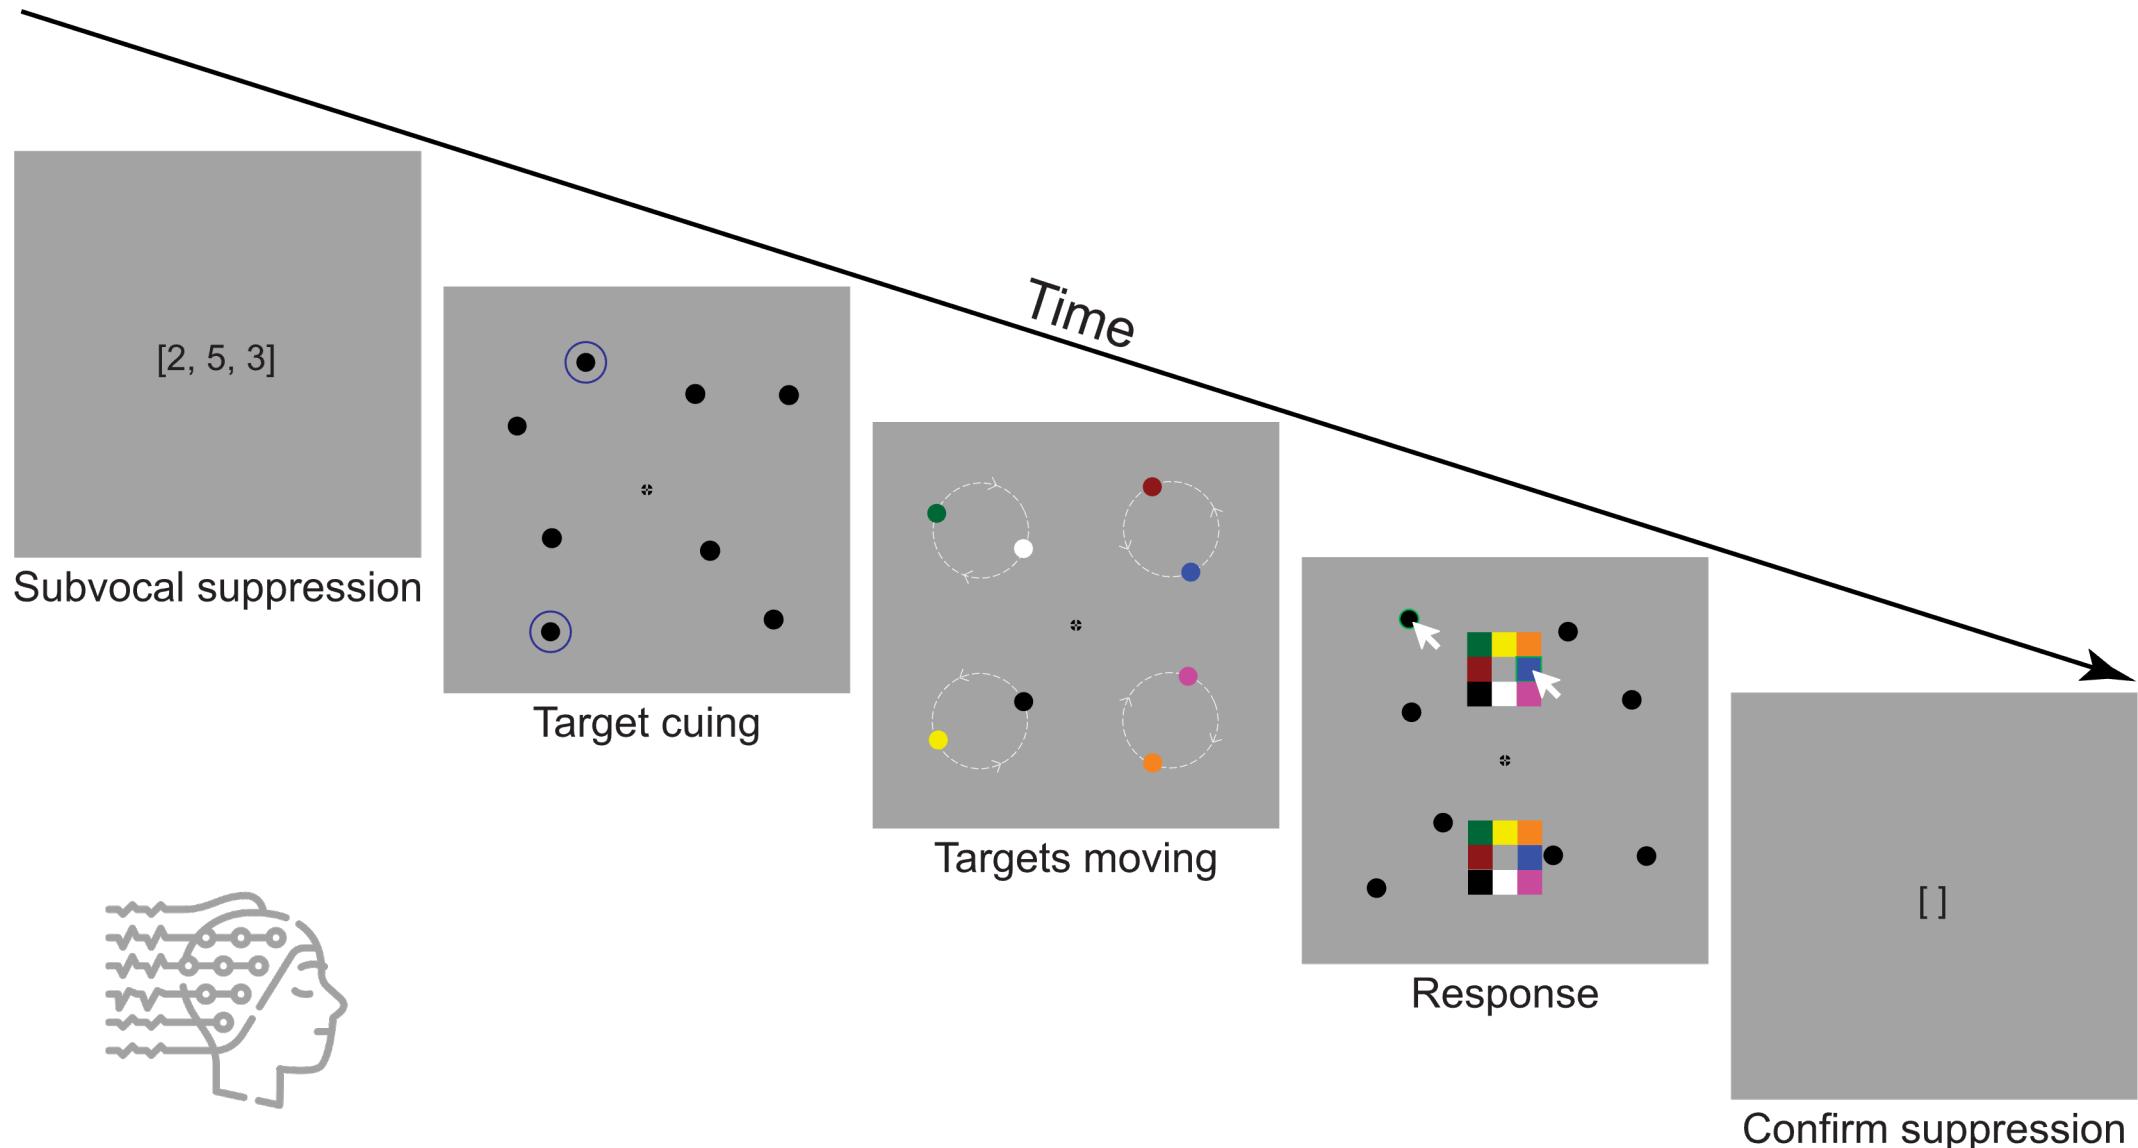

It has been shown that CDA is sensitive to:

- visual working memory load (Vogel & Machizawa, 2004, *Nature*)
- attentional tracking load (Drew & Vogel, 2008, *JoN*)

Drew, Horowitz, Wolfe & Vogel, 2011, *JoN*

Experiment 1 - method

Experiment 1 - method

Attentional tracking only
[click all discs]

1 disc, 2 colors

1 disc, 4 colors

2 discs, 2 colors

2 discs, 4 colors

Attentional tracking and
working memory
[click all discs and all colors]

1 disc, 2 colors

1 disc, 4 colors

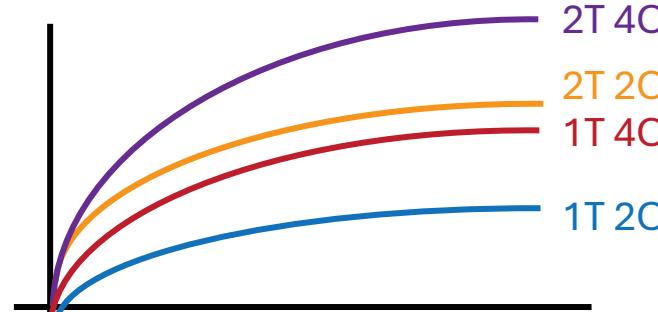

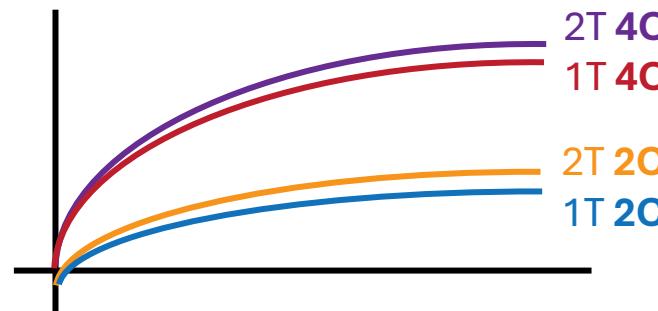

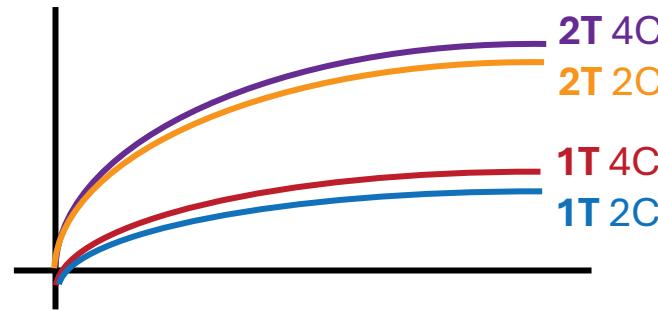

2 discs, 2 colors

2 discs, 4 colors

96 trials per condition 16 blocks
20 participants

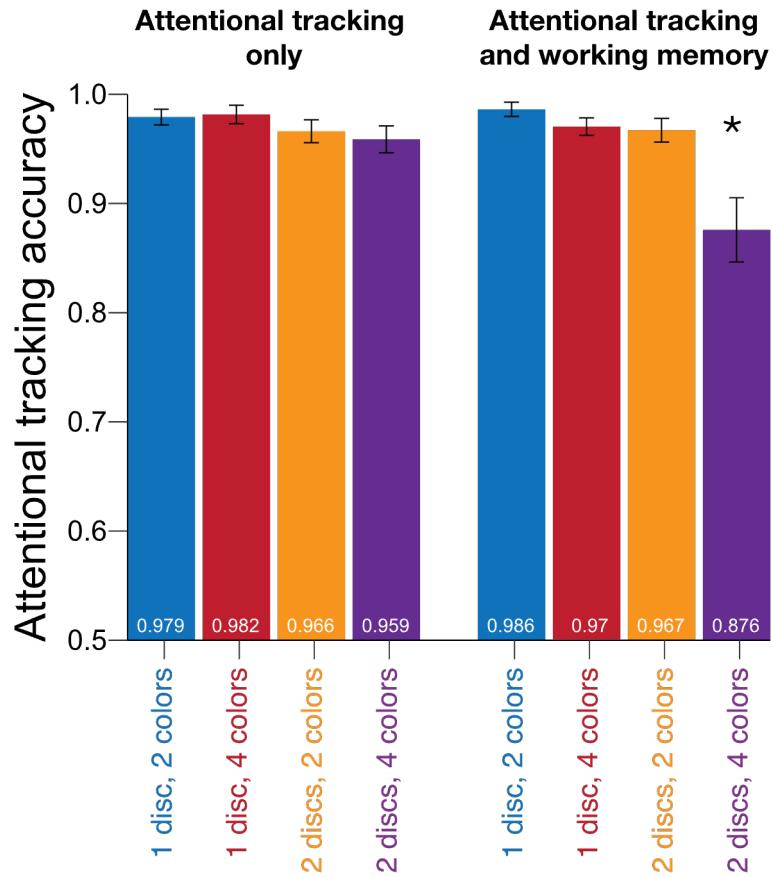

Possible patterns of results

- CDA will reflect mainly attentional tracking load
- CDA will reflect mainly working memory load
- CDA will reflect combined effect of attentional tracking load and working memory load

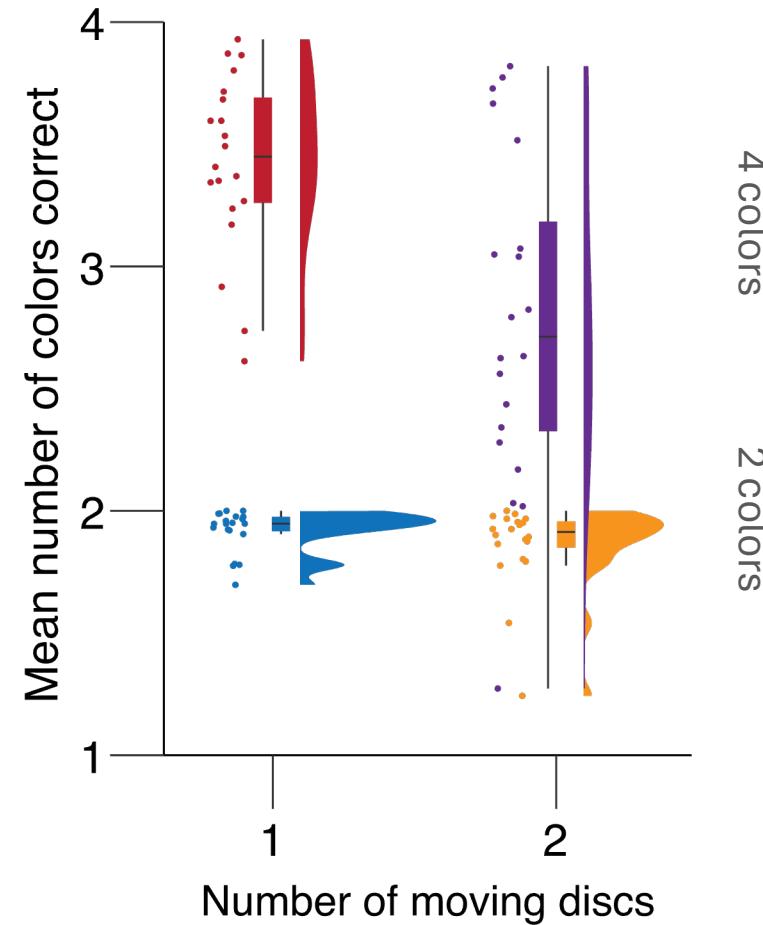

Experiment 1 – behavioral results

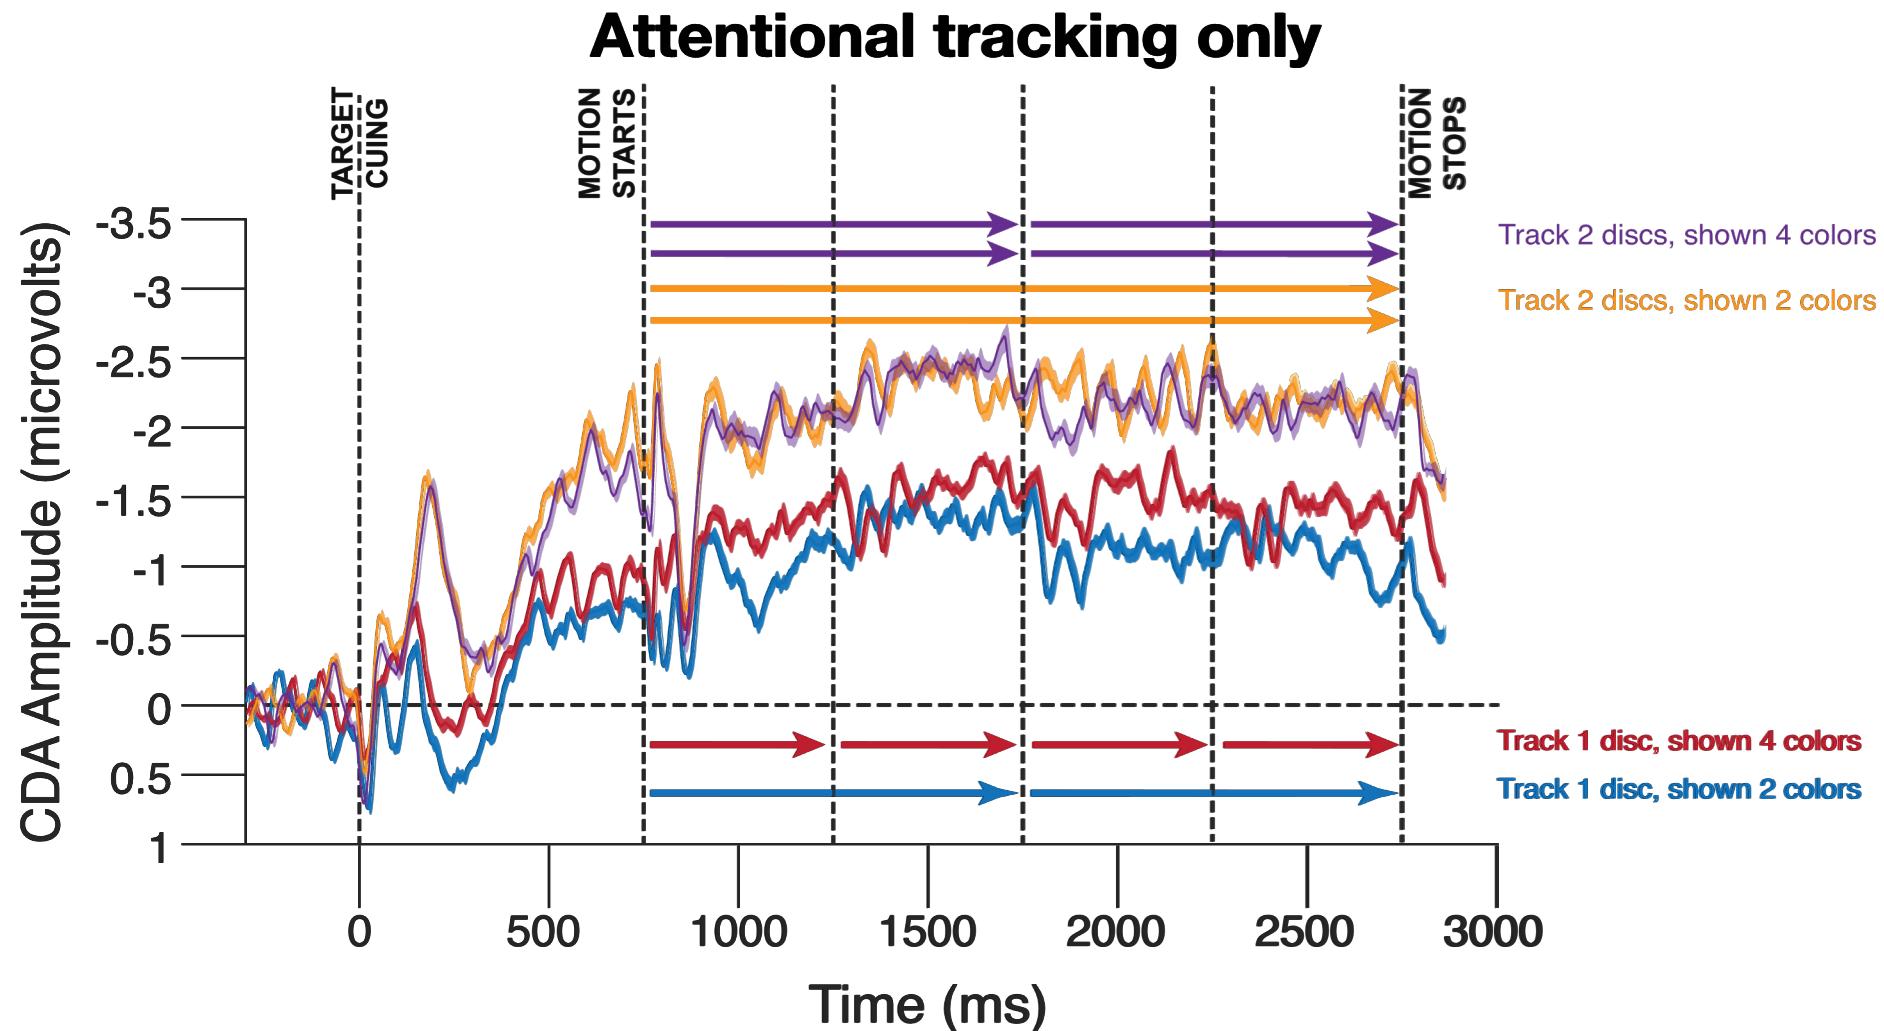

Attentional tracking performance

Working memory performance
(number of colors correct)

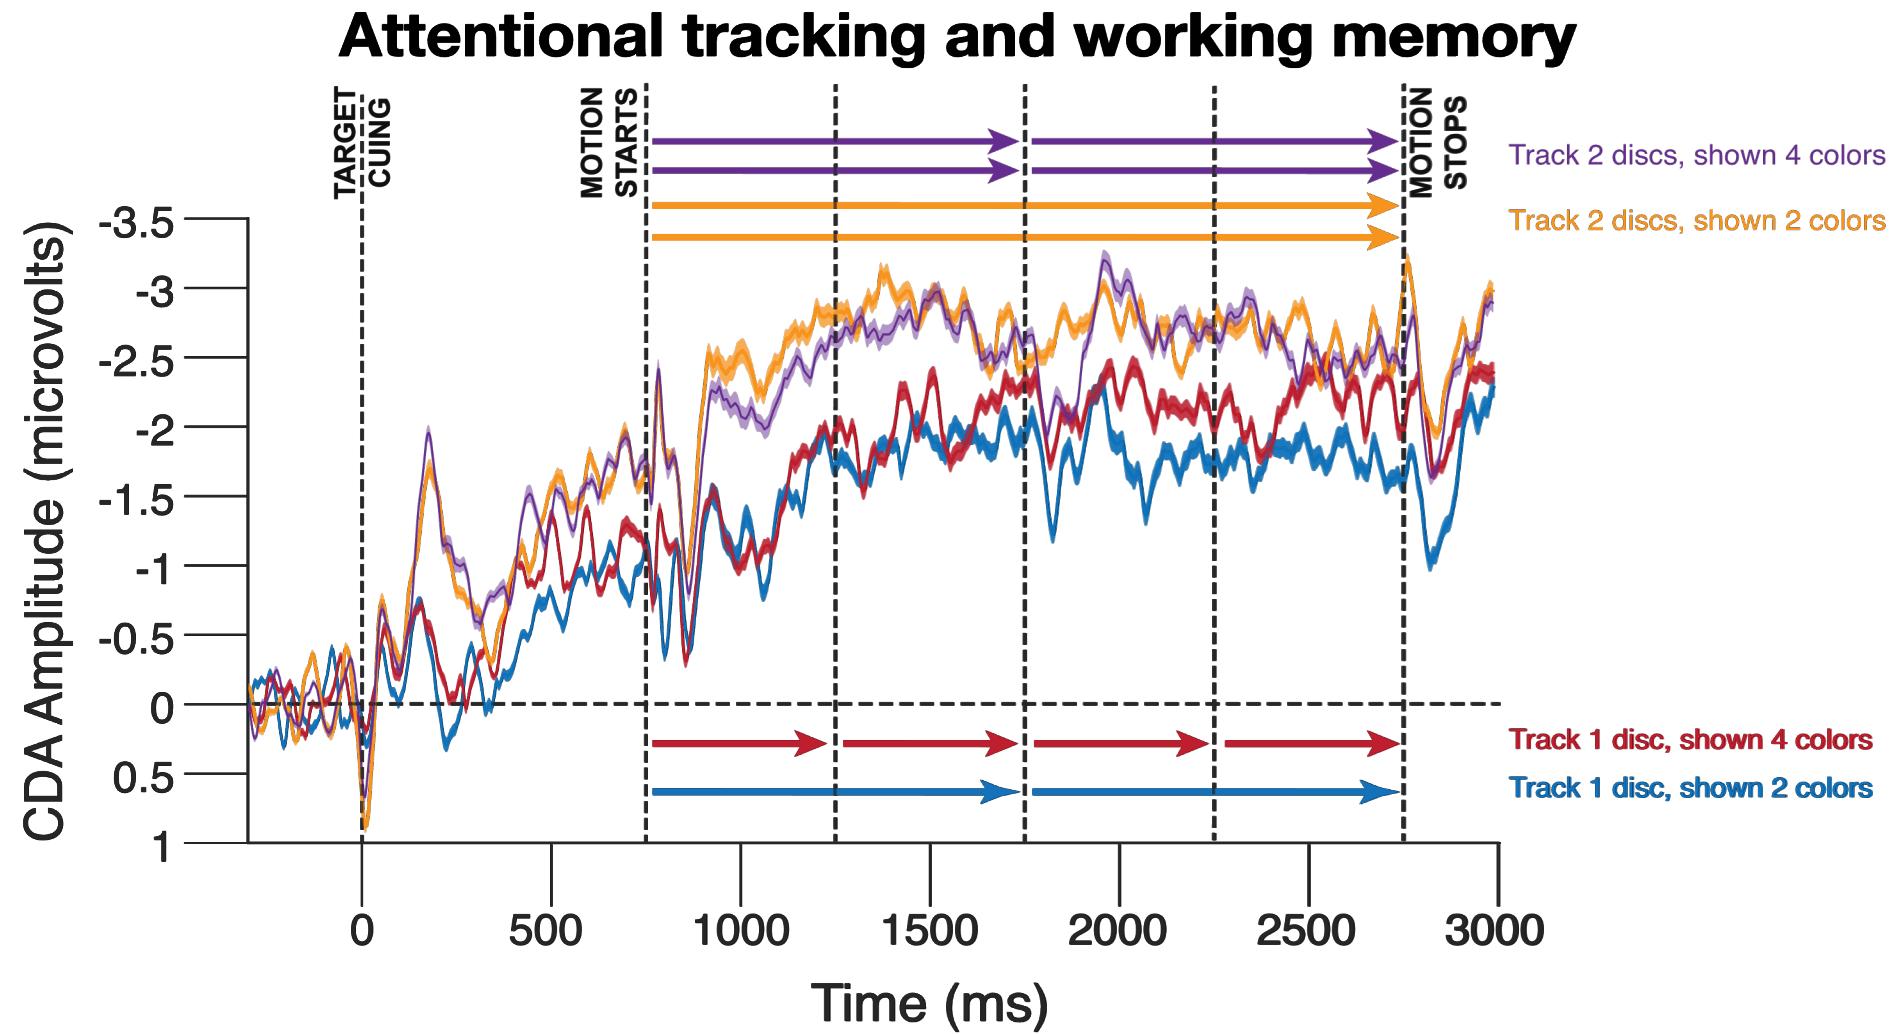

Experiment 1 – EEG results

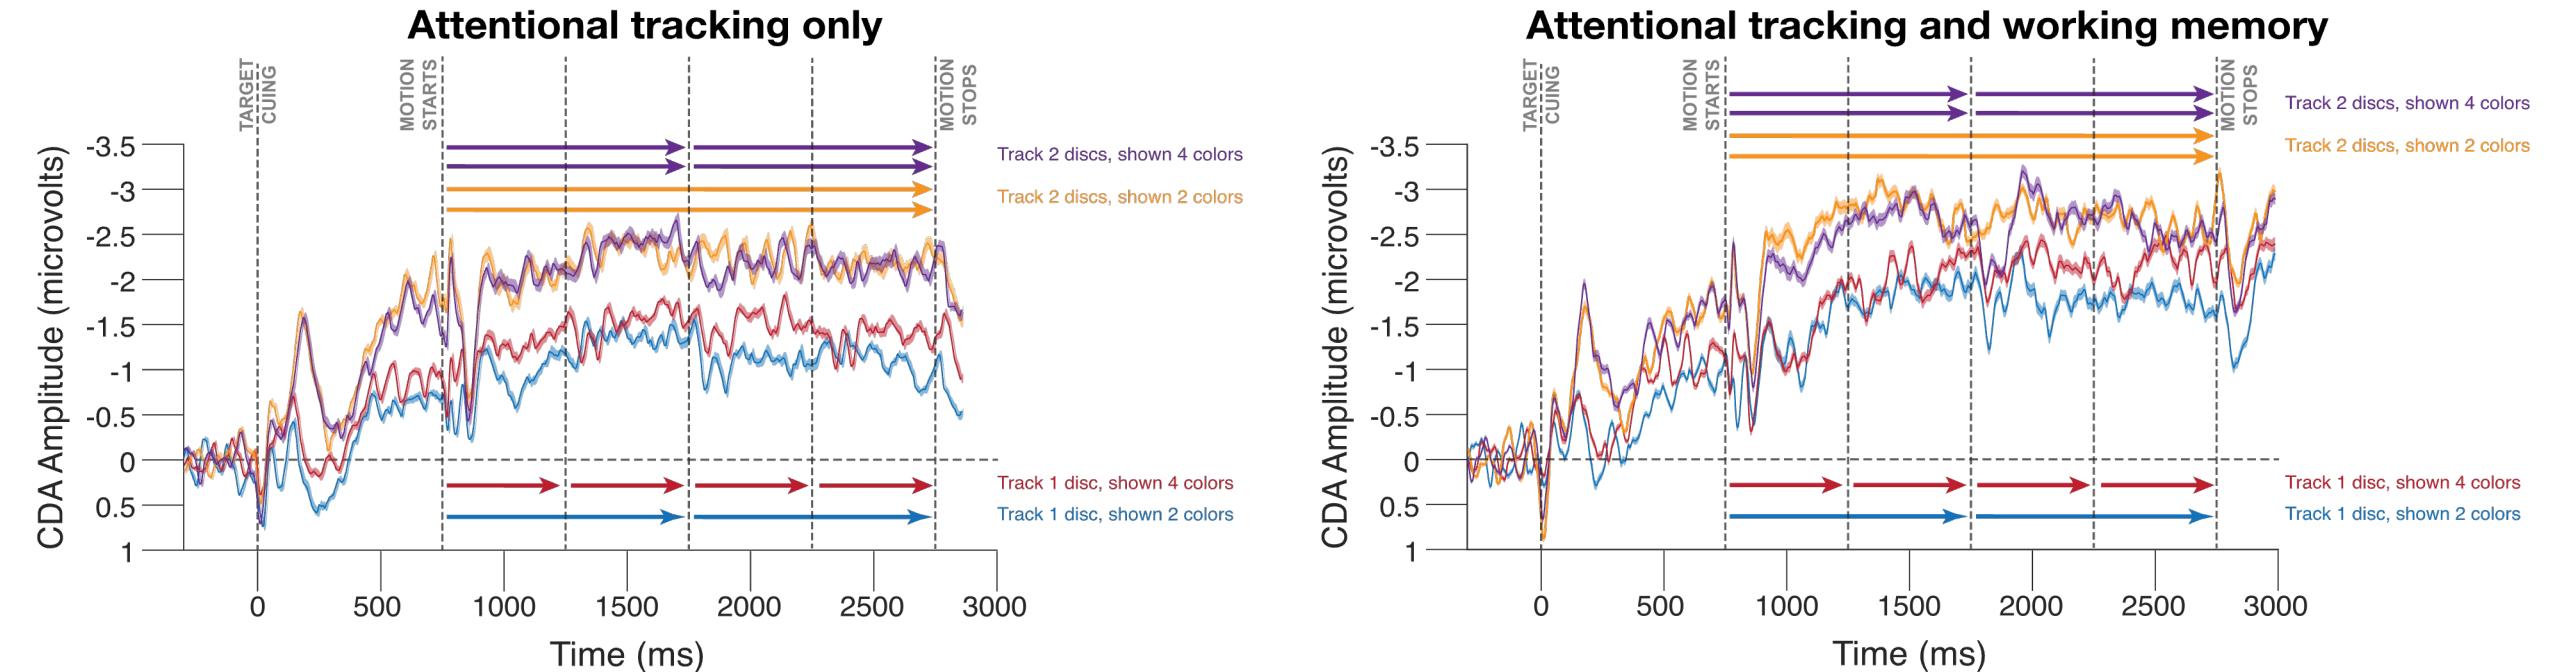

CDA was calculated using the PO3/PO4, PO7/PO8, P3/P4, and P7/P8 electrode pairs

Experiment 1 – EEG results

CDA was calculated using the PO3/PO4, PO7/PO8, P3/P4, and P7/P8 electrode pairs

Experiment 1 – EEG results

CDA was calculated using the PO3/PO4, PO7/PO8, P3/P4, and P7/P8 electrode pairs

Interim conclusions

- In the combined attentional tracking and working memory task, the CDA is primarily driven by the attentional tracking load, not working memory load.
- CDA also captures differences between attentional tracking alone and attentional tracking with working memory
 - This might be due to separate but related cognitive mechanisms associated with these tasks

Experiment 2 - method

[9, 6, 7]

Static conditions
[attend discs and remember
colors]

2 discs, 2 colors
2 discs, 4 colors

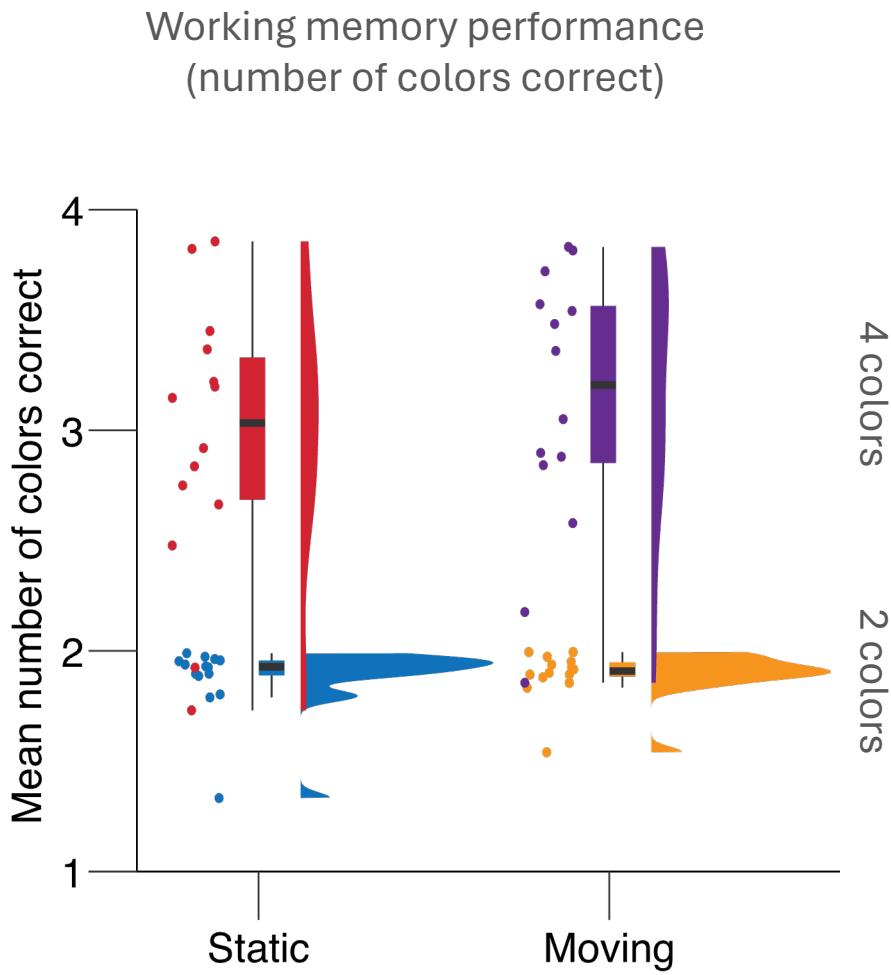

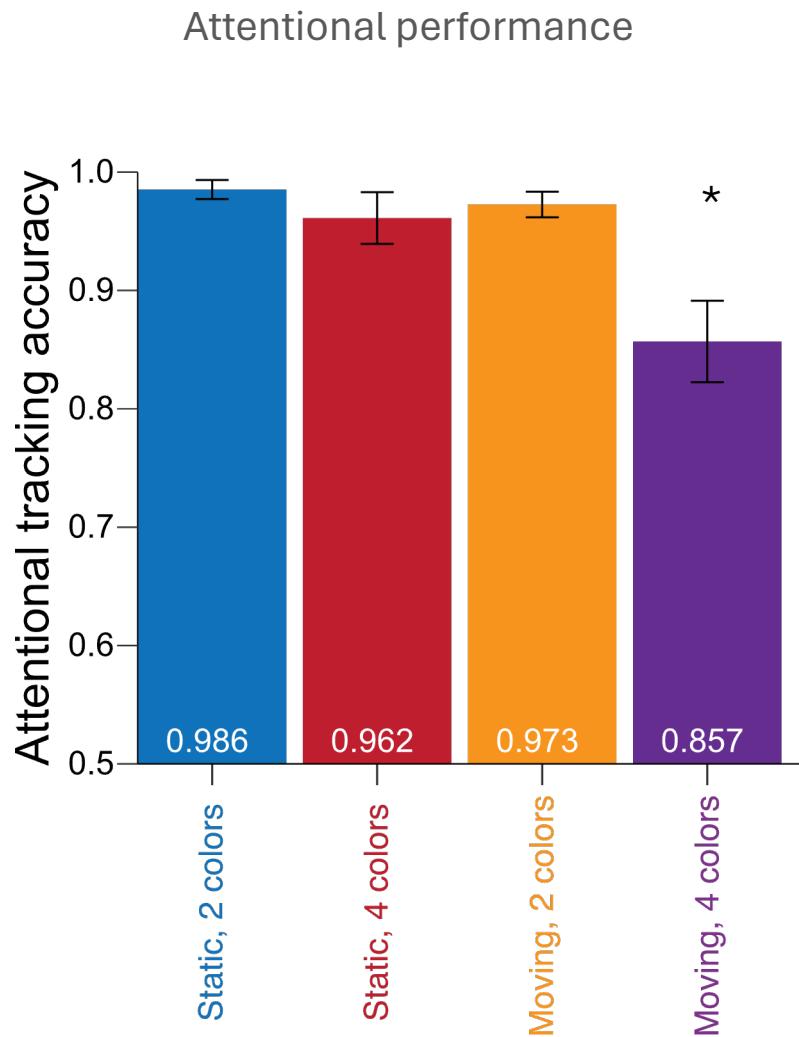

Moving conditions
[track discs and remember
colors]

2 discs, 2 colors
2 discs, 4 colors

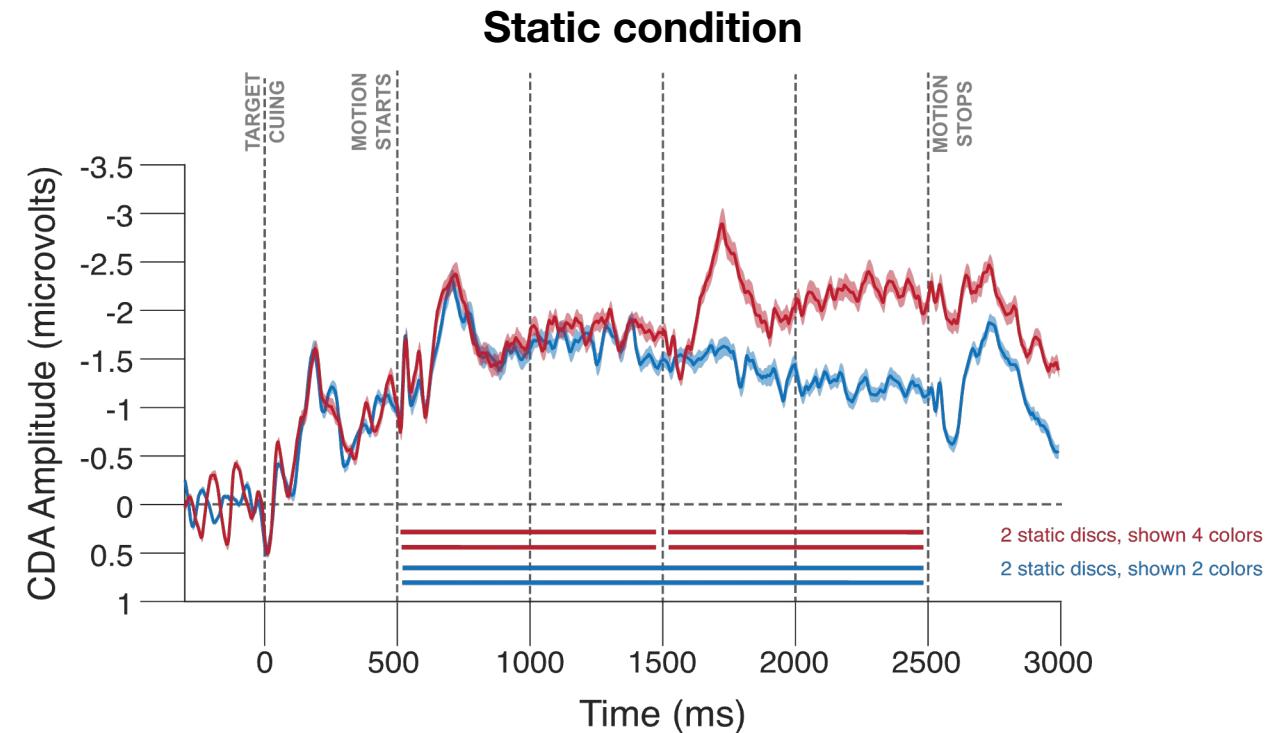

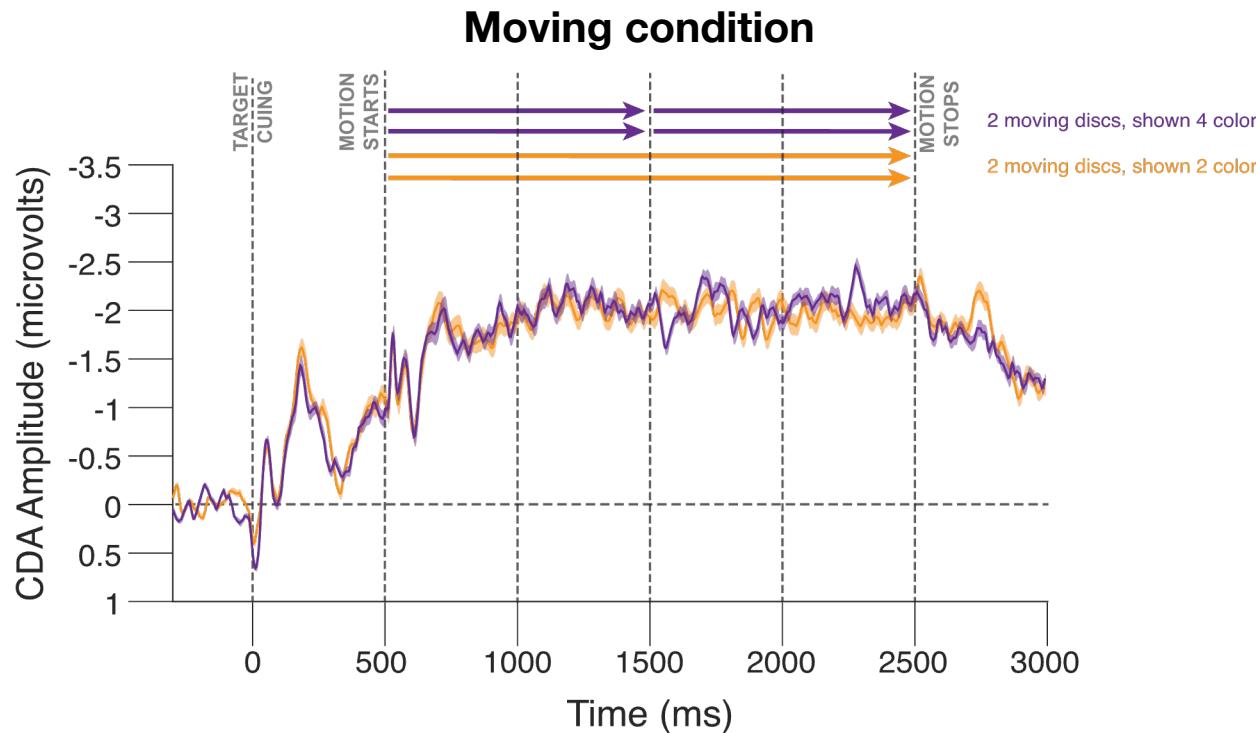

192 trials per condition
16 blocks

14 participants so far

Experiment 2 – behavioral results

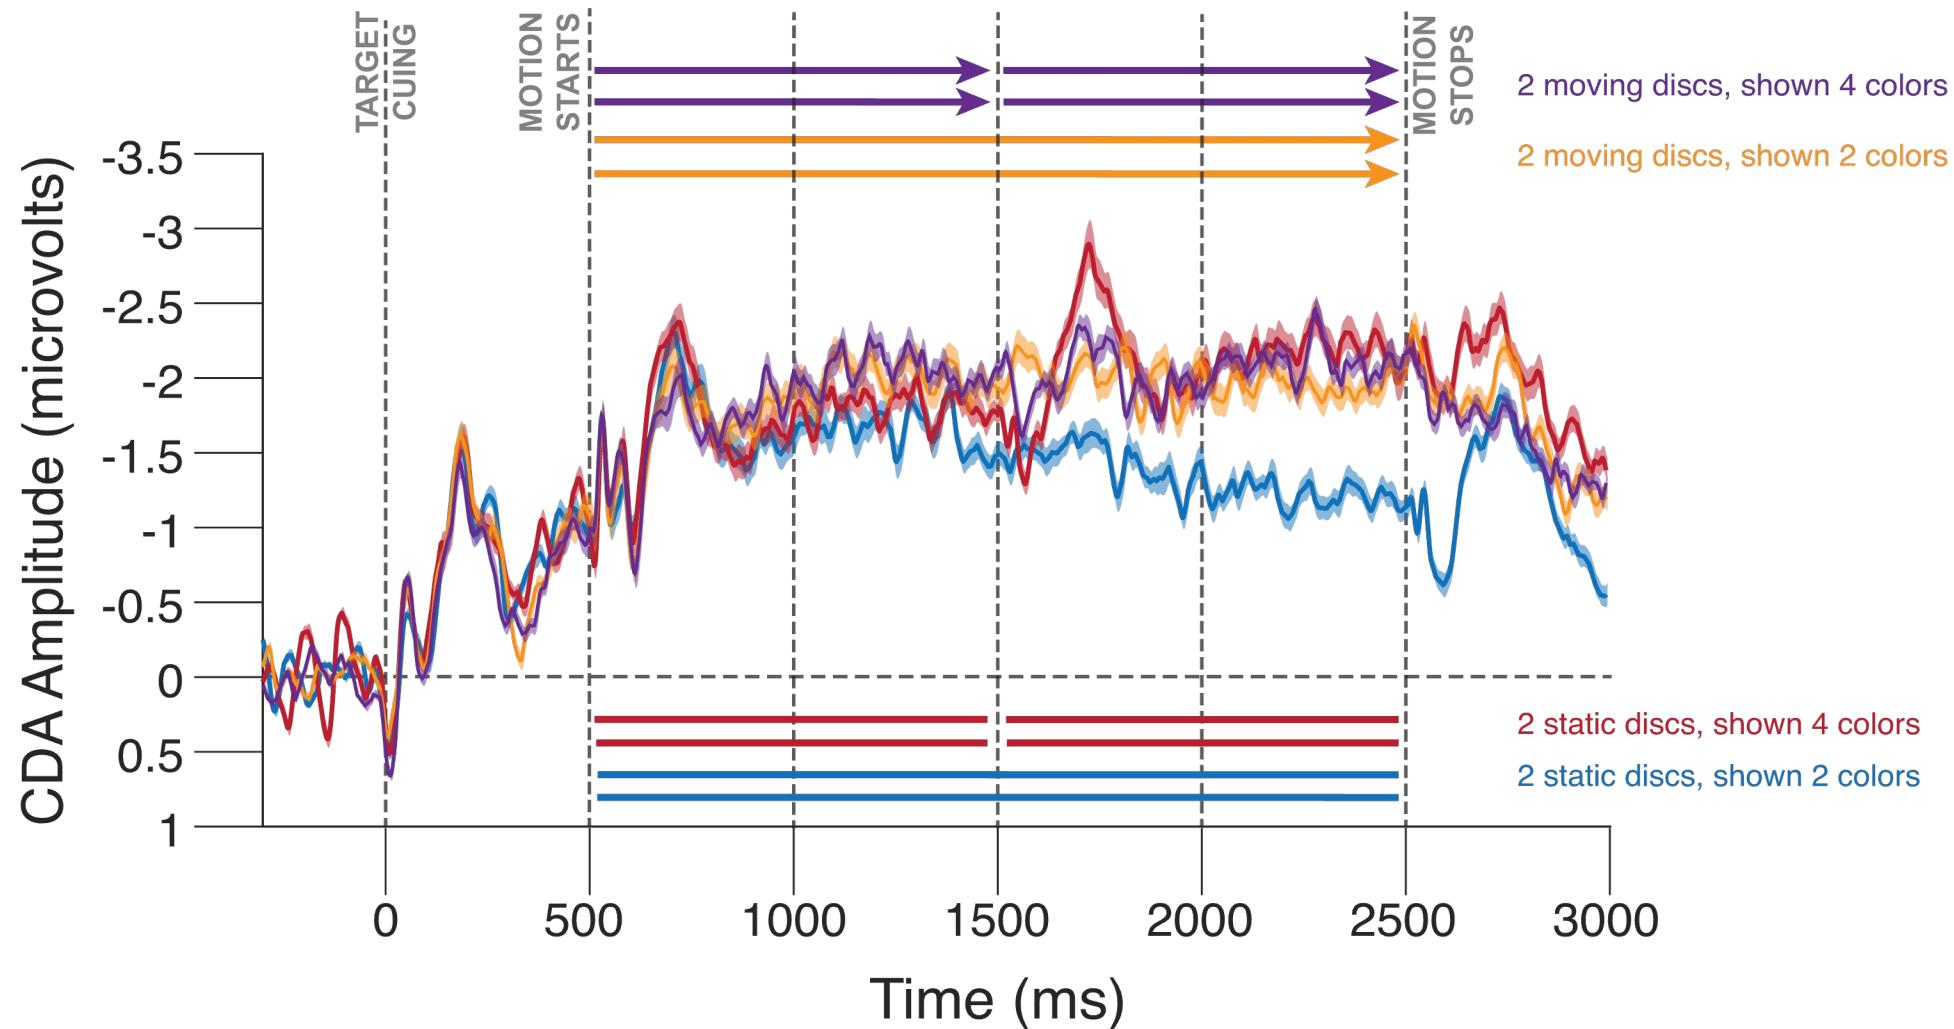

Experiment 2 – EEG results

CDA was calculated using the PO3/PO4, PO7/PO8, P3/P4, and P7/P8 electrode pairs

Experiment 2 – EEG results

Conclusions

- In our new paradigm, Contralateral Delay Activity is dominated by attentional tracking demands when motion is involved
 - When both the number of discs to track and the number of colors per disc are varying, CDA amplitudes are determined by the number of tracked discs
- Why was the CDA not sensitive to the number of colors in Exp. 1?
 - Motion serves as a strong Gestalt cue for objecthood (e.g. motion silencing)
- Spatiotemporal indexing is important both for attentional tracking and visual working memory
 - It remains open if this indexing in attentional tracking and working memory is the same or are different processes
